

Solution to 5g base station power outage

Overview

How do you localize a network outage?

Once an outage is detected, (1c) localizes the outage by identifying the affected users (oUEs), served users (sUEs), and compensating base stations (cBS). Module 2 starts with (2a), determining whether the outage involves a single or multiple base stations. Based on the outage level, the appropriate compensation strategy is selected in (2b).

What is a power outage?

An outage is specifically identified for practical implementation when the reference signal received power falls below a threshold, typically ranging from -120 to -140 dBm, within the coverage area of base stations.

How are outage users divided between compensating base stations?

Outage users are divided equally among the compensating base stations based on proximity. The best possible compensating base station serves each outage user. Each cBS has its own set of sUEs, which, along with its assigned oUEs, form the set of cUEs. Each cBS uses its set of cUEs, JFI, and GM-assisted rewards for training.

How can RSRQ be used to detect cell outages?

By incorporating RSRQ into the cell outage detection algorithm, our system is capable of detecting outages even in congested or interference-heavy environments, ensuring more robust detection. An outage event in our system is when a base station cannot provide adequate service to its connected user equipment.
